

DECARBONISATION OF UK ELECTRICITY (2000-2025)

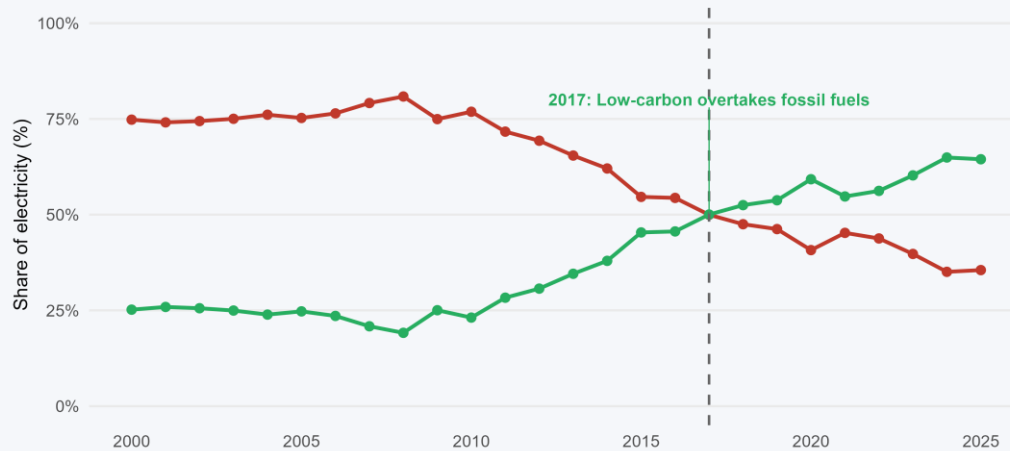

Tracking the shift from fossil fuels to low-carbon energy and its impact on emissions

Electricity generation is a major source of carbon emissions, and the UK has committed to reaching **Net Zero by 2050**. This poster shows how the electricity system has shifted since 2000, from fossil fuels to low-carbon energy, and how this transition has reduced emissions.

UK Electricity Transition

Low-carbon energy overtook fossil fuels in 2017 and continues to grow.

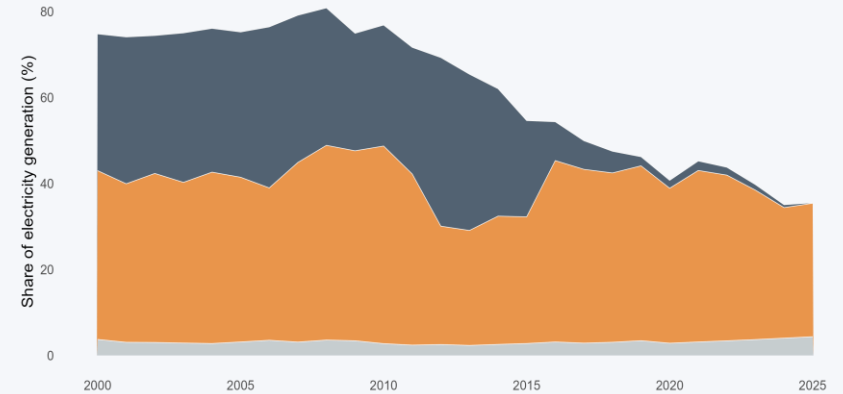

Fossil fuels Low-carbon

Fossil Fuel Composition

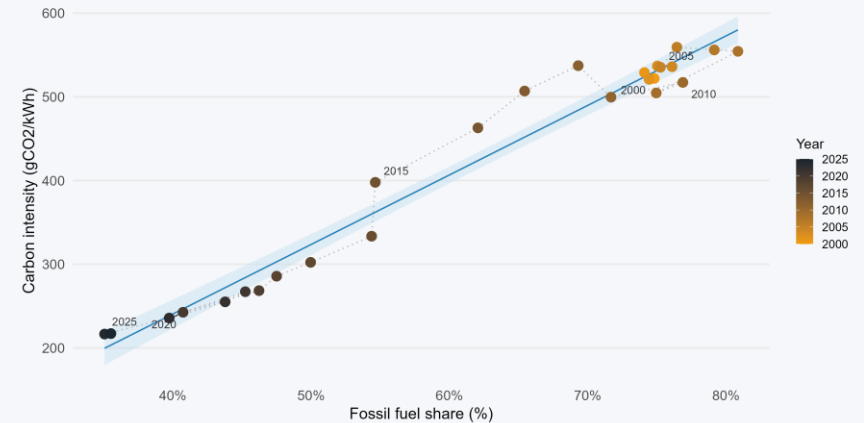

Fossil fuels fall as coal declines, while gas remains dominant.

Coal Gas Oil

Fossil Fuel Share vs Carbon Intensity

Reducing fossil fuels leads to lower emissions

While the UK has significantly reduced electricity emissions through the shift to low-carbon energy, achieving **Net Zero by 2050** will require fully phasing out natural gas.
